Gene Name: SH2D1A

Gene Description: SH2 domain protein 1A

Omim ID: [300490](#), [308240](#)

Gene Ontology: [Hyperlink](#)

Gene Summary: This gene encodes a protein that plays a major role in the bidirectional stimulation of T and B cells. This protein contains an SH2 domain and a short tail. It associates with the signaling lymphocyte-activation molecule, thereby acting as an inhibitor of this transmembrane protein by blocking the recruitment of the SH2-domain-containing signal-transduction molecule SHP-2 to its docking site. This protein can also bind to other related surface molecules that are expressed on activated T, B and NK cells, thereby modifying signal transduction pathways in these cells. Mutations in this gene cause lymphoproliferative syndrome X-linked type 1 or Duncan disease, a rare immunodeficiency characterized by extreme susceptibility to infection with Epstein-Barr virus, with symptoms including severe mononucleosis and malignant lymphoma. Multiple transcript variants encoding different isoforms have been found for this gene. [provided by RefSeq]

Other Designations: Duncan's disease,OTTHUMP00000023976,SLAM-associated protein,T cell signal transduction molecule SAP,signaling lymphocyte activation molecule-associated protein
