SMN2 MaxPab mouse polyclonal antibody (B01) MaxPab®

規格:[50 uL]

Catalog # : H00006607-B01

List All

SMN2 MaxPab polyclonal antibody. Western Blot analysis of SMN2 expression in human kidney.

Protocol Download

Western Blot (Transfected lysate)

15-

Western Blot analysis of SMN2 expression in transfected 293T cell line ($\underline{H00006607-T01}$) by SMN2 MaxPab polyclonal antibody.

Lane 1: SMN2 transfected lysate(31.02 KDa). Lane 2: Non-transfected lysate.

Gene Information

Entrez GeneID: 6607 Gene Bank NM_022875 Accession#: NP_075013.1 Prote in NP_075013.1 Accession#: SMN2 Gene Name: SMN2 Gene Alias: BCD541,C-BCD541,FLJ76644,MGC20996,MGC5208,SMNC Gene survival of motor neuron 2, centromeric Description: 601627 Gene Ontology: Hyperlink Gene Summary: This gene is part of a 500 kb inverted duplication on chromosome 5q13. This duplicated region contains at least four genes and repetitive elements which make it prone to rearrangements and deletions. The repetitiveness and complexity of the sequence have also caused difficulty in determining the organization of this genemic region. The telomeric copies of this gene are nearly identical and encode the same protein. While mutations in the telomeric copy are associated with spinal muscular atrophy, mutations in this gene, the

	Gene Summary:	This duplicated region contains at least four genes and repetitive elements which make it prone to rearrangements and deletions. The repetitiveness and complexity of the sequence have also caused difficulty in determining the organization of this genomic region. The telomeric and centromeric copies of this gene are nearly identical and encode the same protein. While mutations in the telomeric copy are

centromeric copy, do not lead to disease. This gene may be a modifier of disease caused by mutation in the telomeric copy. The critical sequence difference between the two genes is a single nucleotide in exon 7, which is thought to be an exon splice enhancer. Note that the nine exons of both the telomeric and centromeric copies are designated historically as exon 1, 2a, 2b, and 3-8. It is thought that gene conversion events may involve the two genes, leading to varying copy numbers of each gene. The full length protein encoded by this gene localizes to both the cytoplasm and the nucleus. Within the nucleus, the protein localizes to subnuclear bodies called gems which are found near coiled bodies containing high concentrations of small ribonucleoproteins (snRNPs). This protein forms heteromeric complexes with proteins such as SIP1 and GEMIN4, and also interacts with several proteins known to be involved in the biogenesis of snRNPs, such as hnRNP U protein and the small nucleolar RNA binding protein. Four transcript variants encoding distinct isoforms have been described. [provided by RefSeq
